# What we learned:

Floquet Theorem

$$X'' + K(s)X = 0$$

$$K(s) = K(s + L)$$

$$X(s) = aw(s)e^{j\psi(s)}, \quad w(s) = w(s + L), \quad \psi(s + L) - \psi(s) = 2\pi\mu$$

$$\beta(s) = w^2, \quad \alpha = -\frac{1}{2}\beta', \quad \gamma = \frac{1 + \alpha^2}{\beta}, \quad w(s) = \sqrt{\beta(s)}, \quad \psi(s) = \int_{s_0}^s \frac{1}{\beta} ds$$

$$\begin{aligned} \begin{pmatrix} X(s_2) \\ X'(s_2) \end{pmatrix} &= M(s_2, s_1) \begin{pmatrix} X(s_1) \\ X'(s_1) \end{pmatrix} \\ M(s_2, s_1) &= \begin{pmatrix} \sqrt{\frac{\beta_2}{\beta_1}} (\cos \mu + \alpha_1 \sin \mu) & \sqrt{\beta_1 \beta_2} \sin \mu \\ -\frac{1 + \alpha_1 \alpha_2}{\sqrt{\beta_1 \beta_2}} \sin \mu - \frac{\alpha_1 - \alpha_2}{\sqrt{\beta_1 \beta_2}} \cos \mu & \sqrt{\frac{\beta_2}{\beta_1}} (\cos \mu - \alpha_1 \sin \mu) \end{pmatrix} \\ &= \begin{pmatrix} \sqrt{\beta_2} & 0 \\ -\frac{\alpha_2}{\sqrt{\beta_2}} & \frac{1}{\sqrt{\beta_2}} \end{pmatrix} \begin{pmatrix} \cos \mu & \sin \mu \\ -\sin \mu & \cos \mu \end{pmatrix} \begin{pmatrix} \frac{1}{\sqrt{\beta_1}} & 0 \\ -\frac{\alpha_1}{\sqrt{\beta_1}} & \sqrt{\beta_1} \end{pmatrix} \end{aligned}$$

The values of the Courant–Snyder parameters  $\alpha_2, \beta_2, \gamma_2$  at  $s_2$  are related to  $\alpha_1, \beta_1, \gamma_1$  at  $s_1$  by

$$\begin{pmatrix} \beta \\ \alpha \\ \gamma \end{pmatrix}_2 = \begin{pmatrix} M_{11}^2 & -2M_{11}M_{12} & M_{12}^2 \\ -M_{11}M_{21} & M_{11}M_{22} + M_{12}M_{21} & -M_{12}M_{22} \\ M_{21}^2 & -2M_{21}M_{22} & M_{22}^2 \end{pmatrix} \begin{pmatrix} \beta \\ \alpha \\ \gamma \end{pmatrix}_1$$

The evolution of the betatron amplitude function in a drift space is

$$\beta_2 = \frac{1}{\gamma_1} + \gamma_1 \left( s - \frac{\alpha_1}{\gamma_1} \right)^2 = \beta^* + \frac{(s - s^*)^2}{\beta^*},$$

$$\alpha_2 = \alpha_1 - \gamma_1 s = -\frac{(s - s^*)}{\beta^*}, \quad \gamma_2 = \gamma_1 = \frac{1}{\beta^*}$$

Passing through a thin-lens quadrupole, the evolution of betatron function is

$$\beta_2 = \beta_1, \quad \alpha_2 = \alpha_1 + \frac{\beta_1}{f}, \quad \gamma_2 = \gamma_1 + \frac{2\alpha_1}{f} + \frac{\beta_1}{f^2}$$

$$X = \sqrt{2\beta J} \cos \psi, \quad X' = -\sqrt{\frac{2J}{\beta}} (\sin \psi + \alpha \cos \psi)$$

$$P_X = \beta X' + \alpha X = -\sqrt{2\beta J} \sin \psi$$

$(X, P_X)$  form a **normalized phase space coordinates** with  $X^2 + P_X^2 = 2\beta J$ , here  $J$  is called **action**.

## Courant-Snyder Invariant

$$\gamma X^2 + 2\alpha X X' + \beta X'^2 = \frac{1}{\beta} [X^2 + (\alpha X + \beta X')^2] = 2J \equiv \varepsilon$$

Example: Ellipses (vertical) with different optical parameters

The betatron phase space ellipses of a particle with actions  $J = 10\pi$  mm-mrad. The betatron parameters are  $\beta_y = 10\text{m}$ , and  $\alpha_y$  shown by each curve. The scale for the ordinate  $y$  is mm, and  $y'$  in mrad. The betatron parameters for each ellipse are marked on the graph. All ellipses have the maximum  $y$  coordinate at  $(2\beta_y J)^{1/2}$ . The maximum angular coordinate  $y'$  is  $(2(1 + \alpha_y^2)J/\beta_y)^{1/2}$ . All ellipses have the same phase space area of  $2J$ .

# Courant-Snyder Invariant

$$\gamma X^2 + 2\alpha XX' + \beta X'^2 = \frac{1}{\beta} [X^2 + (\alpha X + \beta X')^2] = 2J \equiv \varepsilon$$

## Emittance of a beam

Given a normalized distribution function  $\rho(X, X')$  with  $\int \rho(X, X') dX dX' = 1$ , the moments of the beam distribution are

$$\langle X \rangle = \int X \rho(X, X') dX dX', \quad \langle X' \rangle = \int X' \rho(X, X') dX dX',$$

$$\sigma_X^2 = \int (X - \langle X \rangle)^2 \rho(X, X') dX dX', \quad \sigma_{X'}^2 = \int (X' - \langle X' \rangle)^2 \rho(X, X') dX dX',$$

$$\sigma_{XX'} = \int (X - \langle X \rangle)(X' - \langle X' \rangle) \rho(X, X') dX dX' = r \sigma_X \sigma_{X'}$$

Where  $\sigma_X$  and  $\sigma_{X'}$  are the rms beam widths,  $\sigma_{XX'}$  is the correlation, and  $r$  is the correlation coefficient. The rms beam emittance is then defined as

$$\varepsilon_{rms} = \sqrt{\sigma_X^2 \sigma_{X'}^2 - \sigma_{XX'}^2} = \sigma_X \sigma_{X'} \sqrt{1 - r^2}$$

## The rms emittance is invariant in linear transport:

$$\varepsilon^2 = \sigma_X^2 \sigma_{X'}^2 - \sigma_{XX'}^2$$

$$\sigma_X^2 = \langle X^2 \rangle - \langle X \rangle^2, \quad \sigma_{X'}^2 = \langle X'^2 \rangle - \langle X' \rangle^2, \quad \sigma_{XX'} = \langle XX' \rangle - \langle X \rangle \langle X' \rangle$$

we find

$$\frac{d\sigma_X^2}{ds} = 2\langle XX' \rangle - 2\langle X \rangle \langle X' \rangle$$

$$\frac{d\sigma_{X'}^2}{ds} = 2\langle X'X'' \rangle - 2\langle X' \rangle \langle X'' \rangle$$

$$\frac{d\sigma_{XX'}}{ds} = \langle X'^2 \rangle - \langle X' \rangle^2 - \langle X \rangle \langle X'' \rangle + \langle XX'' \rangle$$

$$X'' + KX = 0$$

$$\frac{d\varepsilon^2}{ds} = \sigma_X^2 \frac{d\sigma_{X'}^2}{ds} + \sigma_{X'}^2 \frac{d\sigma_X^2}{ds} - 2\sigma_{XX'} \frac{d\sigma_{XX'}}{ds} = 0$$

# The Gaussian distribution function

The equilibrium beam distribution in the linearized betatron phase space may be any function of the invariant action. However, the Gaussian distribution function is commonly used to evaluate the beam properties. Expressing the normalized Gaussian distribution in the normalized phase space, we obtain

$$\rho(X, P_X) = \frac{1}{2\pi\sigma_X^2} e^{-(X^2 + P_X^2)/2\sigma_X^2}$$

where  $\langle X^2 \rangle = \langle P_X^2 \rangle = \sigma_X^2 = \beta_X \epsilon_{rms}$  with an rms emittance  $\epsilon_{rms}$ . Transforming  $(X, P_X)$  into the action-angle variables  $(J, \psi)$  with

$$X = \sqrt{2\beta J} \cos \psi, \quad P_X = -\sqrt{2\beta J} \sin \psi$$

The Jacobian of the transformation is  $\beta_X$ , and the distribution function becomes

$$\rho(J) = \frac{1}{\epsilon_{rms}} e^{-J/\epsilon_{rms}}, \quad \rho(\epsilon) = \frac{1}{2\epsilon_{rms}} e^{-\epsilon/2\epsilon_{rms}}$$

The percentage of particles contained within  $\epsilon = n\epsilon_{rms}$  is  $1 - e^{-n/2}$

$\epsilon/\epsilon_{rms}$	2	4	6	8
Percentage in 1D [%]	63	86	95	98
Percentage in 2D [%]	40	74	90	96

The maximum phase-space area that particles can survive in an accelerator is called the *admittance*, or the **dynamic aperture**. The admittance is determined by the vacuum chamber size, the kicker aperture, and nonlinear magnetic fields.

## Adiabatic damping and the normalized emittance: $\epsilon_n = \epsilon \beta \gamma$

The Courant–Snyder invariant, derived from the phase-space coordinate  $X, X'$ , is not invariant when the energy is changed. To obtain the Liouville invariant phase-space area, we should use the conjugate phase-space coordinates  $(X, P_x)$  in Hamiltonian. Since  $p_x = p_x' = mc\beta\gamma X'$ , where  $m$  is the particle's mass,  $p$  is its momentum, and  $\beta\gamma$  is the Lorentz relativistic factor, the *normalized emittance* defined by  $\epsilon_n = \epsilon \beta \gamma$  is invariant. The beam emittance decreases with increasing beam momentum, i.e.  $\epsilon = \epsilon_n / \beta \gamma$ . This is called **adiabatic damping**. Since the transverse velocity of a particle does not change during acceleration, the transverse angle  $X' = p_x / p$  becomes smaller at a higher particle momentum. Thus the beam emittance  $\epsilon = \epsilon_n / \beta \gamma$  decreases with energy. The adiabatic damping also applies to beam emittance in proton or electron **linacs**.

Because of the quantum fluctuation, The beam emittance in electron storage rings **increases** with energy ( $\sim \gamma^2$ ). The corresponding normalized emittance is proportional to  $\gamma^3$ .

# Betatron motion: Effects of Linear Magnetic field Error

$$x'' + K_x(s)x = \frac{\Delta B_y}{B\rho}, \quad y'' + K_y(s)y = -\frac{\Delta B_x}{B\rho}$$

$$\Delta B_y + j\Delta B_x = B_0 \sum_n (b_n + ja_n)(x + jy)^n,$$

$$B_y = B_0 b_0, \quad B_x = B_0 a_0,$$

Dipole field error

$$B_y = B_0 b_1 x, \quad B_x = B_0 b_1 y,$$

Quadrupole field error

~~$$B_y = -B_0 a_1 y, \quad B_x = B_0 a_1 x,$$~~

~~Skew Quadrupole field error~~

~~$$B_y = B_0 b_2 (x^2 - y^2), \quad B_x = 2B_0 b_2 xy,$$~~

~~Sextupole field error~~

~~$$B_y = -2B_0 a_2 xy, \quad B_x = B_0 a_2 (x^2 - y^2),$$~~

$$x'' + [K_x(s) + k(s)]x = \frac{b_0}{\rho}, \quad y'' + [K_y(s) - k(s)]y = -\frac{a_0}{\rho}$$

# Effect of dipole field error:

We consider a single localized dipole error with the kick angle given by  $\theta = \Delta B \ell / B \rho$ . Because of the dipole field error, the reference orbit is perturbed! The idea is to find a new closed orbit that include the dipole field error.

$$X'' + K_X(s)X = \theta \delta(s - s_0)$$

The closed orbit is given by the following condition:

$$\begin{pmatrix} X_0 \\ X'_0 - \theta \end{pmatrix} = M \begin{pmatrix} X_0 \\ X'_0 \end{pmatrix} = \begin{pmatrix} \cos \Phi + \alpha_0 \sin \Phi & \beta_0 \sin \Phi \\ -\gamma_0 \sin \Phi & \cos \Phi - \alpha_0 \sin \Phi \end{pmatrix} \begin{pmatrix} X_0 \\ X'_0 \end{pmatrix}$$

Where  $\Phi = 2\pi\nu$ ,  $\nu$  is the betatron tune, the parameters  $\alpha_0$ ,  $\beta_0$ , and  $\gamma_0$  are values of the Courant-Snyder parameters at the kicker location. The solution is

$$X_0 = \frac{\beta_0 \theta}{2 \sin \pi \nu} \cos \pi \nu,$$

$$X'_0 = \frac{\theta}{2 \sin \pi \nu} (\sin \pi \nu - \alpha_0 \cos \pi \nu)$$

We have solved the closed orbit at one point  $s_0$ . The closed orbit of the accelerator can be obtained by making mapping matrix:

$$\begin{pmatrix} X(s) \\ X'(s) \end{pmatrix}_{\text{co}} = M(s, s_0) \begin{pmatrix} X_0 \\ X'_0 \end{pmatrix} \quad X_{\text{co}}(s) = G(s, s_0)\theta$$

$$G(s, s_0) = \frac{\sqrt{\beta(s_0)\beta(s)}}{2 \sin \pi\nu} \cos[\pi\nu - |\psi(s) - \psi(s_0)|]$$

Note that the closed orbit is described by Green's function. **When the betatron tune is an integer, the closed orbit diverges. Each time, when the particle arrives the same location will receive a coherent kick and the particle becomes unstable.**

**How? And Why**

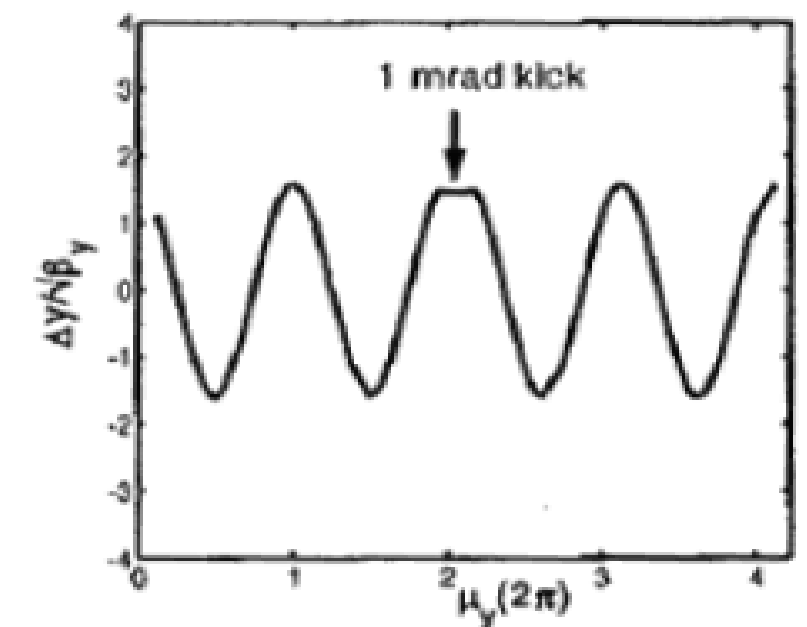

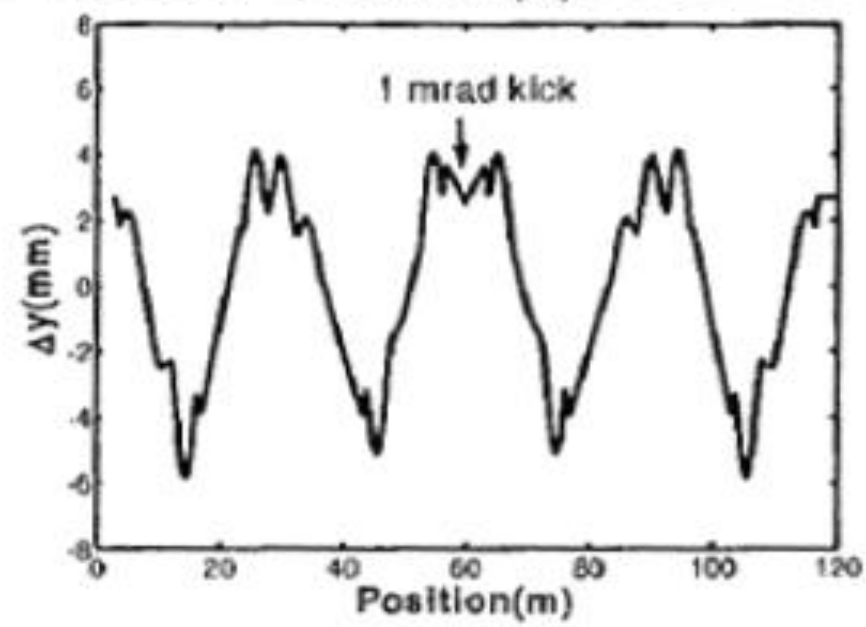

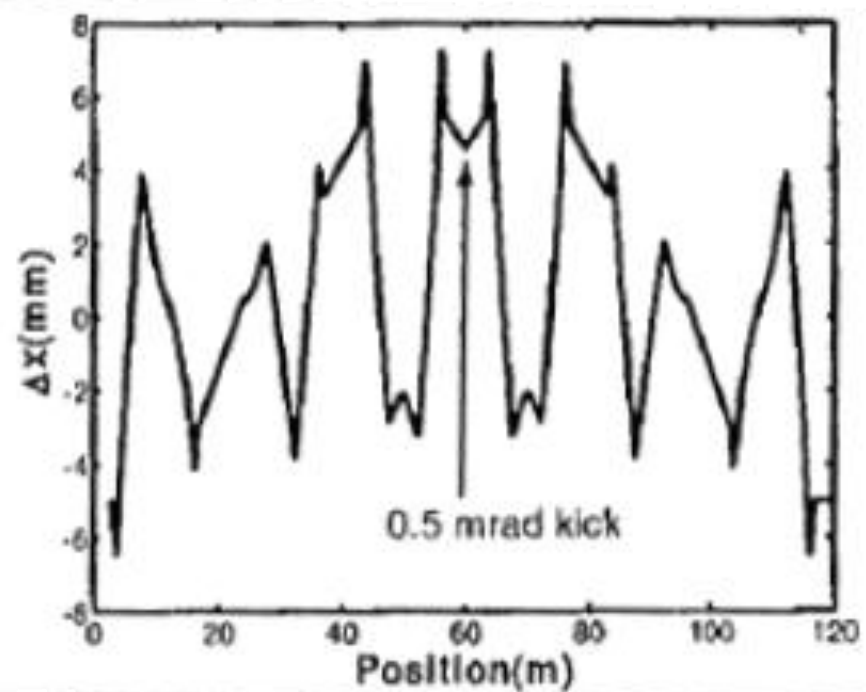

Left, a schematic plot of the closed-orbit perturbation due to an error dipole kick when the betatron tune is an integer. Here  $p_x = \beta_x \Delta X' = \beta_x \theta$ , where  $\theta$  is the dipole kick angle and  $\beta_x$  is the betatron amplitude function value at the dipole. Right, a schematic plot of the particle trajectory resulting from a dipole kick when the betatron tune is a half-integer; here the angular kicks from two consecutive orbital revolutions cancel each other.

An accelerator with circumference 360 m is made of 18 FODO cells. The horizontal betatron tune of the synchrotron is  $\nu_x=4.8$ . If one of the 36 dipoles has an error of -2 mrad and another has error of -1 mrad.

**TLS orbit vs dipole field error:** Lecture note by C.C. Kuo (2002 OCPA Singapore)

Thin lens – use with care

$$\cos \Phi = 1 - \frac{L_1^2}{2f^2}, \quad \sin \frac{\Phi}{2} = \frac{L_1}{2f}$$

In this FOFDO cell with  $L_q=1.0$  m,  $L_{\text{dipole}}=2.0$  m, drift length of 0.25 m, and thus  $L_1=3.5$  m. Thin lens approximation is good except when the focusing strength is high. The percentage error at high focusing gradient can be larger than 11%.

$$L_q=1\text{m}, K_q=1\text{m}^{-2}, L_1=3.5\text{m}$$
