HW 1 (5 point): Future Circular Collider (FCC, ) is under consideration by world physics community as a potentially next high energy collider.

(a) 1 point: The tunnel circumference would be 100 km https://en.wikipedia.org/wiki/Future_Circular_Collider. What average magnetic field is required to circulate 50 TeV proton beam?

The radius of curvature is defined by the particle momentum, charge and magnetic field (Lect 2, eq. (2.3)) and we defined an average “guiding” or “dipole” magnetic filed as defined by the ring circumference, C:

\[
\rho = \frac{pc}{eB_y} = \frac{B \rho}{B_y} \rightarrow d\theta = \frac{ds}{\rho} = \frac{eB_y}{pc} ds \rightarrow \\
2\pi = \oint d\theta = \frac{e}{pc} \oint B_y ds = \frac{eC}{pc} \left\langle B_y \right\rangle
\]

\[
\left\langle B_y \right\rangle = \frac{2\pi \cdot pc}{eC} = \frac{2\pi \cdot B \rho}{C}
\]

Now we can use eq. (2.4) and the fact that \( pc = \sqrt{E^2 - m_p^2 c^4} \equiv E \). Indeed, \( E=50 \) TeV and

\[
E = 50,000 \text{ GeV}; \ m_p c^2 = 938.272046 \text{ MeV} \approx 0.938 \text{ GeV}
\]

\[
\gamma \equiv 5.33 \cdot 10^4 \Rightarrow \frac{E - pc}{E} \equiv \frac{c-v}{c} \equiv 1 - \beta \equiv \frac{1}{2\gamma^2} = 1.76 \cdot 10^{-10}
\]

Then

\[
B \rho [T \cdot km] \equiv \frac{pc[TeV]}{0.299792458} \equiv 167 T \cdot km
\]

\[
\left\langle B_y \right\rangle = \frac{2\pi \cdot B \rho}{C} = 10.48 T
\]

(b) 1 point: It is also considered for electron-positron collider with beam energy up to 175 GeV. What average magnetic field is required to circulate 175 GeV electron or positron beam?

Similarly, electrons are ultra relativistic:

\[
E = 175 \text{ GeV}; \ m_e c^2 = 0.511998910 \text{ MeV} \approx 0.511 \text{ MeV}
\]

\[
\gamma \equiv 3.43 \cdot 10^3 \Rightarrow \frac{E - pc}{E} \equiv \frac{c-v}{c} \equiv 1 - \beta \equiv \frac{1}{2\gamma^2} = 4.26 \cdot 10^{-12}
\]

\[
B \rho [T \cdot km] \equiv \frac{pc[TeV]}{0.299792458} \equiv 0.584 T \cdot km
\]

\[
\left\langle B_y \right\rangle = \frac{2\pi \cdot B \rho}{C} = 0.0367 T = 367 Gs
\]
(c) 2 points: Show that the same ring (set of magnets) can be used to circulate electrons and positrons with the same energy but moving in opposite (colliding) directions. Specifically, write equation of motion for an electron and a positron and show that they can travel by the same trajectory but in opposite directions.

Consider equation of motion on the same trajectory \( \vec{r}_o(t) \) set by magnetic field \( \vec{B}(\vec{r}) \).

Than equation of motion is:

\[
\frac{d\vec{p}}{dt} = \frac{e}{c} \left[ \vec{\nu} \times \vec{B}(\vec{r}) \right]; \vec{\nu}(t) \equiv \frac{d\vec{r}_o(t)}{dt}; \vec{p}(t) = \gamma m \vec{\nu}(t)
\]

Since energy is preserved in magnetic field (neglecting radiation!) than \( \gamma = \text{const} \) and velocity is a function of the trajectory

\[
\frac{d^2\vec{r}_o(t)}{dt^2} = \frac{e}{\gamma mc} \left[ \vec{\nu} \times \vec{B}(\vec{r}) \right] = \frac{e}{\gamma mc} \left[ \frac{d\vec{r}_o(t)}{dt} \times \vec{B}(\vec{r}_o(t)) \right]; \vec{\nu}(t) \equiv \frac{d\vec{r}_o(t)}{dt} = \vec{\nu}(\vec{r}_o(t)) \quad \text{(I)}
\]

Now let change signs of the particle charge \( e \rightarrow -e \) and velocity \( \vec{\nu} \rightarrow -\vec{\nu} \) to derive equation of motion for an antiparticle in the same m

\[
\frac{d^2\vec{r}_o(t)}{dt^2} = -\frac{e}{\gamma mc} \left[ -\vec{\nu} \times \vec{B}(\vec{r}_o) \right] = -\frac{e}{\gamma mc} \left[ \frac{d\vec{r}_o(t)}{dt} \times \vec{B}(\vec{r}_o) \right];
\]

Now we can set antiparticle on the reverse trajectory:

\[
\vec{r}_o(t) = \vec{r}_o(t_o - \tau)
\]

where \( t_o \) is an arbitrary constant and check that its identical to equation of the particle (I):

\[
\frac{d^2\vec{r}_o(t_o - \tau)}{dt^2} = -\frac{e}{\gamma mc} \left[ \frac{d\vec{r}_o(t_o - \tau)}{dt} \times \vec{B}(\vec{r}_o(t_o - \tau)) \right]; \tau = t_o - \tau; dt = -d\tau
\]

\[
\frac{d^2\vec{r}_o(\tau)}{d\tau^2} = \frac{e}{\gamma mc} \left[ \frac{d\vec{r}_o(\tau)}{d\tau} \times \vec{B}(\vec{r}_o(\tau)) \right]
\]

(II)

In short, the changing signs of the particle charge and velocity does not change the value and the direction of the force and trajectory bends the same way.

(d) 1 point: Can be the same trick used to circulate and collide two proton beams?

No, the sign of the force changes for proton propagating in the opposite direction. It means that its trajectory will bend in opposite direction: dipole separator. Surprisingly, electric field would do the trick, but it is not useful for high energies: 10 T filed corresponds to electric field of 3,000 MV/m!
HW 2 (2 points): For a classical microtron having energy gain per pass of 1.022 MeV and operational RF frequency 3 GHz (3 x 10^9 Hz) find required magnetic field (Hint: use k=1). What will be radius of first orbit in this microtron?

Solution: Again, lets start from the radius of curvature

\[ \rho = \frac{p_c}{eB_y} \]

and calculate time of flight for a given energy

\[ T = \frac{2\pi \rho}{v} = \frac{2\pi}{eB_y} \cdot \frac{p_c}{v} = \frac{2\pi}{eB_y} \cdot \frac{E}{c} \]

The energy at n-turn is equal to the rest energy electron energy 0.511 MeV plus n-fold energy gain:

\[ E_n = mc^2 + n \cdot \Delta E; \quad \Delta E = 2mc^2; \]

\[ E_n = (2n+1)mc^2 = (2n+1) \cdot 0.511 \text{MeV} \]

Now we should use synchronization condition, e.g. that each turn should take an integer number of RF cycles

\[ T_n = N(n) \cdot T_o; \quad T_o = \frac{1}{f_{RF}}; \quad T_n = \frac{2\pi}{eB_y} \cdot \frac{E_n}{c} = (2n+1) \frac{2\pi mc}{eB_y}; \]

\[ N(n) = k \cdot (2n+1); \quad \frac{2\pi mc}{eB_y} = kT_o \rightarrow B_y = \frac{1}{k} \frac{2\pi mc^2}{e(cT_o)} \]

where k is a positive integer. Putting number together for k=1, we get for first pass

\[ cT_o = \frac{c}{f_o} = 9.993 \text{cm} \equiv 10 \text{cm}; \]

\[ \frac{2\pi mc^2}{e} = 2\pi \frac{0.511...}{0.29979...} = 2\pi \cdot 1.705 \text{ kGs cm} = 10.71 \text{ kGs cm} \]

\[ B_y \equiv 1.071 \text{ kGs} \]

\[ \gamma = 2n+1 \Rightarrow \gamma_1 = 3; \quad \beta_1 = \sqrt{1-\gamma_1^2} \equiv 0.943 \]

\[ p_1c = \gamma_1 \beta_1 mc^2 \equiv 1.445 \text{ MeV} \]

\[ \rho_1[cm] = \frac{p_1c[MeV]}{0.3 \cdot B_y} = 4.5 \text{ cm} \]

The other way to find radius of first orbit: it takes 3 RF periods and orbit circumference is

\[ T_1 = 3 \cdot T_o; \quad C_1 = 2\pi \rho_1 = v_1T_1 = \beta_1cT_1 = 26.26 \text{ cm} \]

Naturally, dividing the circumference by 2π we get the same 4.5 cm radius of the first orbit.
HW 3 (3 points): Find available energy (so called C.M. energy) for a head-on collision of electrons and protons in two proposed electron-hadron eRHIC and LHeC:

(a) eRHIC plans to collide 20 GeV electrons with 250 GeV protons;
(b) LHeC plans to collide 60 GeV electrons with 7 TeV protons

\[ p_p^\mu = \left\{ E_p / c, p_p, 0, 0 \right\}; \quad p_e^\mu = \left\{ E_e / c, -p_e, 0, 0 \right\} \]

First let’s find the c.m. energy using 4-momenta of both particles:

\[ p_e^\mu = \left\{ E_e / c, -p_e, 0, 0 \right\}; \quad p_p^\mu = \left\{ E_p / c, p_p, 0, 0 \right\}; \]

\[ p_e^\mu = \left\{ \frac{E_p + E_e}{c} , p_p - p_e, 0, 0 \right\}; \quad E_{cm}^2 = p_e^\mu p_e^\mu = \left( \frac{E_p + E_e}{c} \right)^2 - \left( p_p - p_e \right)^2; \]

\[ E_{cm}^2 = (E_p + E_e)^2 - (p_p c - p_e c)^2 = E_p^2 - (p_p c)^2 + E_e^2 - (p_e c)^2 + 2(E_p E_e + p_p p_e c^2) \]

\[ E_p^2 - (p_p c)^2 = \left( m_p c^2 \right)^2; \quad E_e^2 - (p_e c)^2 = \left( m_e c^2 \right)^2; \]

\[ E_{cm}^2 = \frac{m_p^2 c^4 + m_e^2 c^4 + 2E_p E_e \left( 1 + \beta_p \beta_e \right)}{2}; \]

\[ E_{cm} = \sqrt{m_p^2 c^4 + m_e^2 c^4 + 2E_p E_e \left( 1 + \beta_p \beta_e \right)} \]

For ultra-relativistic case (\( \gamma_p >> 1; \gamma_e >> 1, 1 - \beta_p \beta_e << 1 \)) we can approximately write

\[ E_{cm} = 2 \sqrt{E_p E_e} \]

(a) eRHIC with 20 GeV electrons and 250 GeV protons:
Exact \( E_{cm} = 141.4242197 \) GeV, approximate 141.4213562 is accurate in 5 digits.

(b) LHeC with 60 GeV electrons with 7 TeV protons: \( E_{cm} = 1.296 \) TeV GeV.
Difference between exact and proximate formulae 2.6E-7 is negligible.
